Subject: Project DAAG46-80-C-0043  
Letter Progress Report #1

Dear Al:

At the time of writing all DLT specimens have been fabricated, slotted and checked for dimensional accuracy. Initial tests on twelve selected specimens have been conducted. The results obtained are presented in Table I. For comparison purposes, an extract from a table presented in the final report of project DAAG46-78-C0045 is also presented (Table II) for plate S-I. The latter table presents averages and ranges for a non-textured ESR 4340.

The following tentative observations may be drawn at this time:

- (i) Three of the four transverse textured specimens tested (2-45X, 2-LY) show elongation values which fall below the end of the range indicated for the LY orientation in plate S-I.
- (ii) Fracture of ligaments in the short transverse textured specimens tested (TZ and 45Z) occurred below the level of general yielding in the ligaments concerned. This and the subsequent recording of low elongation values (0.5 to 1.8%) are especially noteworthy.
- (iii) Preliminary SEM fractography shows clear evidence of the texturing of prior austenite grains, but otherwise shows somewhat similar features to those seen for plate S-I of the non-textured material.

The above observations should be considered tentative at this time. Prior to a proposed visit by yourself to Georgia Tech we will test further selected specimens representative of the remaining orientations as well as supplementary tests on those orientations already examined. Complementary check tests will be also conducted

Page 2  
Letter Progress Report #1

by Mr. Oppenheimer on his DLT rig. SEM fractography will be available for inspection at that time.

We look forward to seeing you on October 21st,

Yours truly,

John T. Berry,  
Professor

Letter Progress Report #2

Dear Al:

At the present time all of the sixty-four (64) Double Ligament Test (DLT) specimens have been tested in our examination of the transverse engineering properties of the textured high strength AISI ESR 4340 steel plates, samples C and S. The test results are presented here in tabular form (Tables I and II).

We were also able to examine the results of some SEM work which has been undertaken in connection with the testing. A limited number of the DLT specimens were also tested using the DLT rig located in Mr. E. D. Oppenheimer's Mamaroneck facility for check tests.

The results of all tests conducted on the two textured plates may be briefly summarized as follows:

- 1) For the eight (8) different orientations the mechanical properties fall into the ranges detailed in Table III. The data indicates that the textured material has higher ultimate tensile strength and yield strength than does the non-textured AISI ESR 4340 steel in the X and Y-directions. (Refer to our final report on Project DAAG46-78-C-0045.) However, the strength in the short transverse (ST) specimens is inferior, where the fracture often occurred below the general yielding level of the ligaments.
- 2) The short transverse (ST) specimens frequently showed a flat fracture, which sometimes occurred in the bottom of their respective ligaments even though the specimens were adequately gripped and the tests correctly executed.
- 3) The elongation in the (ST) directions have alarmingly low values, as do the associated fracture loads.

- 4) There were no significant testing difficulties applying the DLT to the textured AISI ESR 4340 steel at a  $H_{RC} \approx 57$ .
- 5) With regards to the fracture appearance, an SEM examination has been conducted which shows clear evidence of certain inclusions that affect the strength and ductility of the textured material in the (ST) direction. Further work will eventually be required using SEM fractography and possibly auger spectroscopy to distinguish inclusion fibering from texturing of prior austenite grains and to correctly characterize the phenomena involved.

We look forward to hearing from you.

Yours truly,

John T. Berry  
Professor

## PREFACE

The present writer (J. T. Berry) and his students would like to acknowledge the support received from AMMRC during the conduct of the present project. The counsel, cooperativeness and infinite patience of the present monitor, Mr. A. A. Anctil, are worthy of special note. The author must also acknowledge the provision of facilities at Georgia Tech by Dr. S. P. Kezios, Director of the School of Mechanical Engineering.

The entire bulk of the mechanical testing associated with the present project was undertaken by Mr. Issam Fadel, masters student in the School of Mechanical Engineering. Without Mr. Fadel's diligent work and careful scrutiny this work could not have been performed. Together with Mr. Y. Shimazaki, Mr. Fadel undertook the preliminary SEM study. The final SEM study was performed by Mr. J. Hubbard of the Georgia Tech Engineering Experimental Station, for whom we have special commendation. Special thanks should also be conveyed to Mr. Ed Oppenheimer for his counsel on testing aspects, to Messrs. Harry Vaughan and Virgil McCollum for their part in the exacting task of producing the DLT specimens from pre-hardened plate and finally to Mrs. Rosie Atkins for her incredible care in generating clear accurate manuscripts with the very minimal guidance from the author.

## ABSTRACT

The objective of the current investigation was to determine the transverse properties of electroslag remelted AISI 4340 which had been processed to produce an intense (112) + (111) type texture. The material was processed from 10 inch (250 mm) x 5.0 inch (125 mm) x 5.0 inch (125 mm) thick slabs to approximately 0.5 inch (12.5 mm) thick plate in a two high rolling mill to produce the above texture. Utilizing the double ligament test; long transverse, short transverse, longitudinal and diagonal mechanical properties were determined.

The results of the tests indicate that some anisotropy does exist in the plane of the plate. The associated levels of longitudinal yield stress and ultimate stress are considerably higher than those of a non-textured material of corresponding longitudinal ductility and hardness level ( $\sim H_{RC} 57$ ). The long transverse and short transverse ductilities are, however, lower than those of the non-textured material. In the case of the short transverse properties, both inferior strength and ductility were observed.

The associated scanning electron microscopy showed the presence of minute flattened strip-like MnS inclusions on the macroscopically flat or terrace type fracture surfaces associated with the low ductility short transverse specimens. All of the specimens concerned with this orientation broke at stresses below the level of general yielding.

## 1. INTRODUCTION

The present investigation was concerned with the determination of the transverse properties of electroslag remelted AISI 4340\* which had been processed to produce a crystallographic preferred orientation/texture or fibering.

The processing of the two plates received from AMMRC involved the rolling of two ESR 4340 slabs approximately 10.0 inch (250 mm) x 5.0 inch (125 mm) wide x 5.0 inch (125 mm) thick, using a thermomechanical process which results in an intense (112) + (111) type texture [1]. The processing was accomplished on a two-high rolling mill using a ninety percent reduction. The treatment involved was undertaken at the United States Steel Corporation. The hardness of the material (as received) was  $\sim H_{RC} 57$ . Prior to delivery to Georgia Tech the plates ( $\sim 0.5$  inch or 12.5 mm thick) were surface ground at AMMRC to approximately 15/64 inch ( $\sim 6$  mm) thick such that the central section of the plate would be tested using the DLT bars (0.2 inch,  $\sim 5$  mm in thickness). The DLT specimen blanks were cut from the plate so that longitudinal, transverse, and both diagonal blank orientations were obtained. Slots were then cut so that properties in the longitudinal, transverse, diagonal or short transverse directions could be determined. In this way the following type DLT bar designations arise:

TX  
TZ  
LY  
LZ  
45X  
45Z  
315X  
315Z

---

\* Chemical analyses are given in Tables I and II.

In the first four of the designations, the first letter indicates the bar orientation (T = transverse, L = longitudinal) whilst the letter indicates the direction in which the ligaments are cut and ultimately tested (X, Y or Z). The last four orientations represent bars which are oriented in what might be termed a diagonal ( $45^\circ$ ) manner, the 45 and 315 designated bars are mutually orthogonal. The slots were then cut and the bars subsequently tested so that 45X and 315X type bars provided information on the in-plane diagonal properties, whilst the 45Z and 315Z provided information on short transverse properties as are obtained from diagonally oriented specimens (see Figure 1).

The techniques used for specimen fabrication were essentially those described in an earlier work [2] excepting that the rough machining phase involved slitting and facing with abrasive wheel type tooling in view of the hardness of the as-received plate.

The DL testing technique has also been described elsewhere [3,4]. The tests were conducted upon a calibrated 10,000 lb Instron testing machine using a crosshead speed of 0.02 in/min ( $\sim 0.5$  mm/min).

## II. RESULTS

The results of the present tests are summarized in Tables III and IV with respect to individual orientations. Both averages (four specimens per individual orientation) and ranges are shown.

A more compact alternative summary of properties is exhibited in Tables V and VI, wherein further averaging of groups, for example averages of both diagonal orientations combined, are presented (see also Figures 2 and 3).

The raw data from which these tables (III to VI) are constructed is shown in the appendix in Tables A-I and A-II. The bar locations are also detailed in the appendix (Figures A1 and 2).

The results of scanning electron microscopy are included in the accompanying discussion.

### III. DISCUSSION AND CONCLUSIONS

It is interesting to compare the data collected in Tables III through VI with those reported upon previously [1] for a non-textured plate (S-I) of ESR 4340 of equivalent hardness level.

It will be seen that the levels of longitudinal yield and ultimate stresses are considerably higher than those of the non-textured material, which as well as being of equivalent hardness, is of roughly equivalent longitudinal ductility.

A further significant difference exists between the short transverse properties exhibited by the non-textured plate of ESR 4340 S-I previously investigated and those exhibited by the textured plates C and S, in spite of the fact that all three plates received roughly similar total amounts of reduction during processing to plate.

Two interesting differences do surface however on comparing chemical analyses and actual rolling/forging schedules. In the first instance sulphur levels for one of the textured plates is somewhat higher than that of the non-textured material (although none of the sulphur levels can be considered high in terms of ESR practice [5,6]). In the second instance there is a profound difference in the way in which the final reduction to size was brought about. The textured plates experienced a severe final reduction of the order of 90%. Such a continuous reduction would promote pronounced flattening of plastic inclusions (MnS) and would not permit any readjustment of inclusion shape which could conceivably take place where there was a forging/rolling schedule with numerous interstage reheatings. (Although it should be mentioned that such adjustment of shape would be limited unless heating extended into the homogenization range. Nonetheless the effect should not be overlooked, since the plate S-I did obviously receive intermediate reheats in pressing and cross-rolling [2]). It should also be noted that the cross-rolling experienced by the plate of non-textured material would also promote a differently shaped inclusion to that expected with material reduced without rotation in the X-Y plane.

Some interesting pointers do emerge when the SEM studies of each

set of fractures are examined. The somewhat flat short-transverse direction fracture appearance in plate C of the textured material frequently exhibited the presence of terraces bearing strip-like streaks (Figure 4a). The streaks could be differentiated from the dimpled but highly oriented prior austenite grain envelopes by their smooth but sometimes perforated appearance (Figures 4b and c). Plate S showed fewer examples of flattened inclusions than did plate C. It will be recalled that although the short-transverse direction fractures of the non-textured plate S-I showed flat spots, sometimes quite extensive, closer examination of those areas revealed a larger local volume fraction of globular rather than the plate shaped inclusions (Figures 5a and b).

In view of the significant part thought to be played by the terraces and flattened streaks seen in the textured material, further electron microscopy was undertaken using more versatile instrument (Cambridge Steroscan as opposed to bench type ISI) which also had available an analysis system (Envirotech attachment) which could examine and characterize X-radiation excited by the electron-beam (Figures 6 and 7).

Reference to the scanning electron micrography in the region of the perforations suggested that the strip-like streaks, if they were in fact inclusions, were extremely thin. The x-ray analysis of the streaks themselves, the underlying regions (areas of perforation) and the regular machined surface (plate C) revealed the presence of manganese and sulphur within the streaks themselves, suggesting very strongly that the streaks were in fact highly elongated very thin manganese sulphide type inclusions. (The outputs of the respective analyses are shown in Figures 8 to 10.)

The thin nature of the subject inclusions in the Z or short-transverse direction can also be appreciated from the color ordinary light photomicrography of Figure 11 which would seem to indicate a typical thickness of  $\sim 1\mu$ . Reference to the literature [7] suggests that ribbon like MnS inclusions of this morphology may be of the harmful so-called type II variety promoted by low oxygen contents.

Consequently, it is concluded that the presence of these film like MnS lamellae contributes significantly to the low elongations witnessed in the through thickness DLT tests. At this point, however, the role played by the remaining features of the highly oriented microstructure cannot be elucidated. Possibly TEM work upon this aspect would prove valuable if further development is desired. Furthermore, additional SEM study of the sulphides prior to and after the texturing treatment would be valuable to determine their exact type and origin. Similarly study of rare-earth treated--or alternatively ultra low sulphur--feed stock heats used in conjunction with the ESR and texture inducing process would also be valuable, especially in view of the extremely encouraging strength, ductility combinations seen in the X and Y direction property evaluations of the textured material.

Turning to the in-plane aspects of the mechanical properties determined for the plates C and S, it will be seen that the averaged ultimate stresses showed the diagonal (45X + 315X) direction values to lie intermediate between the longitudinal and transverse values (Figures 2 and 3). This was also true for the yield stress values to plate C. In the case of plate S averaged values were all within 4 Ksi, that is within 1-1/2 percent of each other.

The significant contrast is undoubtedly that seen on comparing the in-plane elongation values, where the transverse (LY) values show a fairly marked inferiority to those of the longitudinal and diagonal orientations. It will also be seen again that plate C shows inferior ductility values overall to those of plate S within the plane of the plate.

It is concluded that:

1. The texturing treatment applied to the subject material results in yield and ultimate stress values in the longitudinal direction of the plate, substantially greater than those of non-textured material of similar hardness level ( $H_{RC} \sim 57$ ) examined previously.
2. The ductility of the textured material in the longitudinal direction is of a similar level to that of the non-textured material, in spite of its superior strength levels.

3. The averaged yield and ultimate stresses of the in-plane samples indicate some degree of anisotropy for plate C at least, where the averaged UTS values for the diagonal orientations (45X + 315X) are intermediate with respect to those of the longitudinal and transverse direction values.
4. In-plane ductility values measured indicate that the transverse (LY) ductility is inferior to those of the longitudinal and diagonal orientations.
5. The significant findings of the present investigation, however, hinge upon the poor ductility and inferior tensile strength witnessed in the short-transverse direction. This is apparent not only on comparison with mechanical properties observed within the plane of the plate but on comparison with the short transverse properties of the non-textured material investigated previously.
6. The macroscopically flat or faceted fractures associated with this behavior, show extensive indications of terracing. Upon undertaking higher-power scanning electron microscopy of the terraced areas of the fracture, strip- or ribbon-like streaks become apparent. These features appear to be minute flattened MnS inclusions, which may be responsible, at least in part, for the low ductility concerned in the short transverse orientations.

 FS = 4096 10 eV/ch

Figure 8. Energy dispersive X-ray analysis output for suspected inclusion area shown in Figure 7(b). Units of abscissa are KeV. Note presence of sulfur peak.

Figure 9. Energy dispersive X-ray analysis output for area associated with perforation in inclusion shown in Figure 7(b). Note absence of sulfur peak.

Figure 10. Energy dispersive X-ray analysis output for machined surface of DLT specimen #29.

x 992

Figure 11. View of MnS inclusion as seen in ZX plane of typical DLT bar sample. Note also highly directional nature of prior austenite grain structure.

## APPENDIX

In the accompanying tables and sketches are included raw data on mechanical properties as determined, range information, as well as bar location information.

Note: When ligaments did not break simultaneously, the data reported is that for the first ligament to break. This principally involves short transverse samples only, but is an important point of procedure, since these values were then entered into the subsequent computations of ranges and averages. The tables attached to previous progress reports on this project generally reported average values of UTS, etc. where separate ligament fracture occurred. Tables included in the final report on the non-textured material, (reference two) dealt with such occurrences on the bases used in the attached tables, that is reporting data on the ligament breaking first only. Data on the second ligament breaking is available if required for further computation for both investigations.
